S1 Comparison of headgroup order parameters from different force fields to experiments

The poor performance of headgroup order parameters in Berger model can be probably explained by ring like structures seen in Fig. 6 in Ref. ? , which is a typical feature for Berger based lipid force fields containing explicit hydrogen atoms in the head group. ? ? ? The poor performance of glycerol backbone of Slipids simulations is systemically observed also for other lipids in previous studies.^{7,13}

1.Should we comment more the relative quality of different force fields and/or make the subjective force field ranking figures? <https://github.com/NMRLipids/NMRLipidsIVPEandPG/issues/8>

Figure S1: The headgroup and glycerol backbone order parameters of PE lipids from experiments (POPE and signs this work, DPPE from Ref. 1 and E.coliPE from Ref. 2) and simulations with different force fields.

2.This should be clarified as in NMRlipidsI and error bars should be added. Probably larger error bars for united atom models based on the report by Fuchs et al.

Figure S2: The headgroup and glycerol backbone order parameters of PG lipids from experiments (POPG and signs from this work and from Ref. 3, DPPG with 100mM NaCl from Ref. 4, and E. Coli PG results from Ref. 2). and simulations with different force fields.

S1.1 PC headgroup interactions with PE and PG

In experiments, the PC headgroup order parameters increase with the addition of negatively charged PG or PS lipids, but are not affected by the addition of zwitterionic PE and SM

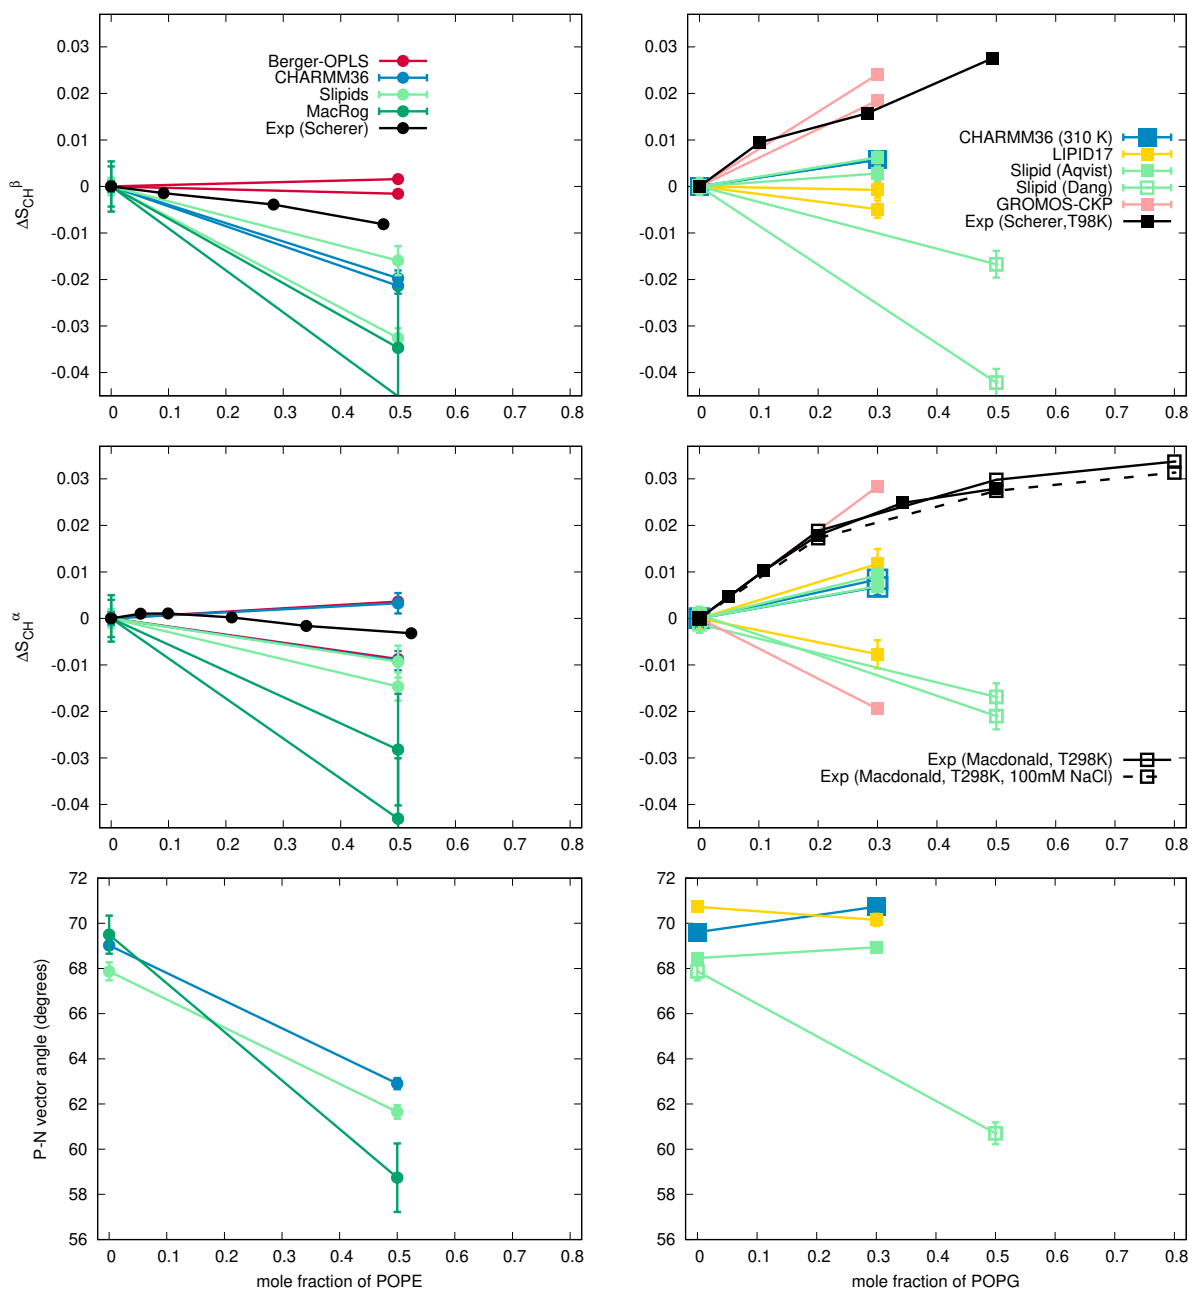

Figure S3: Modulation of POPC headgroup order parameters with increasing amount of POPE (left) and POPG (right) in bilayer from experiments^{5,6} and simulations with different force fields. Signs are determined as discussed in.^{7,8}

3.P-N vector angles from Berger-OPLS and GROMOS-CKP simulations are yet to be analyzed.

lipids or cholesterol (Fig. S3). This can be explained by the electrometer concept, which suggests that the headgroup dipole tilts more parallel to the membrane plane upon addition of negative charge to the membrane.^{5,9,10} The response of PC headgroup order parameters to PE by the tested CHARMM36 and Berger-OPLS force fields, although CHARMM36 slightly overestimates the changes (Fig. S3). The good performance of Berger-OPLS simulations is notable because the response of headgroup order parameters to cholesterol was significantly overestimated by the Berger/HÅültje force field in our previous work.⁷ **4. This is text by P. Fuchs, copied from the blog.**

Area results in nm², the error is <= 0.003 nm²

- pure POPC

CHARMM36: 0.624

Berger : 0.649

- POPC/POPE 50:50

CHARMM36 : POPC 0.609, POPE 0.557

Berger-hacked: POPC 0.637, POPE 0.632

One can see that CHARMM 36 predicts a drop in the area on going from pure POPC to POPC/POPE 50:50. This means that POPC pack tightly to POPE. In contrast, the values for Berger are not that changed. The POPE value predicted by CHARMM 36 (in the mixture POPC/POPE 50:50) is much smaller than that predicted by Berger.

The experimental acyl chain order parameters for POPE¹¹ seem larger than reported for POPC,¹² which supports the more condensed PE bilayer. This is interesting, but not exactly the core message of the manuscript. Maybe we should mention this very briefly? For example, we could just report the areas per lipid (without distinguishing PC and PE) and mention the difference between CHARMM36 and Berger. I have opened an issue for this: <https://github.com/NMRLipids/NMRLipidsIVPEandPG/issues/7>

None of the force fields fully reproduces the PC headgroup order parameter response to

the increasing amount of PG, which may be related to the counterion binding affinity (see also the next section).¹³ In all force fields except Slipids, the order parameters of different hydrogens attached to the α -carbon are responding differently when mixed with PE or PG lipids 5. Maybe we should figure out what is the reason for this?

Maybe we should analyze the P-N vector angle from different simulations?

<https://github.com/NMRLipids/NMRLipidsIVPEandPG/issues/10>.

For β -carbon order parameter in PG headgroup, experiments report mild increase⁶ or no change³ upon addition of PC lipids (Fig. S4). Simulations with all the tested force fields give only very small changes also for the α -carbon order parameter (Figs. S10 and S4). Therefore, the simulations are generally in line with experiments, suggesting that the interactions with PC do not essentially effect the PG headgroup structure. This suggests that the interactions between PG and PC headgroups are captured better in simulations than for PS headgroup, where all the force fields significantly overestimated the structural response of PS headgroup to the interactions with PC lipids.¹⁰

Figure S4: Modulation of PG lipid headgroup order parameters with the increasing amount of PC in lipid bilayer from experiments^{3,6} and simulations with different force fields.

6.P-N angles from Slipids and GROMOS-CKP yet to be calculated.

S1.2 Sodium binding to PE and PG lipid bilayers

Sodium binding affinity to PE lipids has not been measured experimentally, but large differences to PC would be surprising. In simulations, the sodium binding affinity to POPE depends on the used force field (Fig. S5), but lesser extend than reported previously for PC.¹⁴

7.This will be finished once we have all the simulation details and Lipid17 simulations with correct dihedrals from issue <https://github.com/NMRLipids/NMRLipidsIVPEandPG/issues/12>, Because some simulation and ion parameters are not identical with the previous work,¹⁴ we compare POPE results to the POPC simulations ran with identical parameters (Fig. S11). In Lipid17 with the strongest sodium binding affinity to POPE, the binding affinity is approximately similar to POPC. Slipids and CHARMM36 exhibit slightly, and GROMOS-CKP substantially weaker binding to POPE than to POPC. Assuming that the binding to POPE would be similar than to POPC, the sodium binding affinity to POPE is potentially realistic in CHARMM36, Slipids, and GROMOS-CKP simulations here, but substantially overestimated in Lipid17 simulation.

Simulations with PG lipids give similar dependence on force field as observed in POPE simulations: Lipid 17 simulations with Dang ion parameters exhibits stronger counter-ion binding affinity to pure POPG bilayer than CHARMM36, Slipids, and GROMOS-CKP simulations, which are roughly similar (Fig. S6). Lipid17 also exhibits less increase in POPC headgroup order parameters upon addition of POPG than other simulations (Fig. S3), and lower area per molecule (59.5 \AA^2) than in experiments (66.1 \AA^2). In our previous study about PS lipids,¹⁰ such behaviour was related to the overestimated counterions binding and shielding the electrostatic repulsion between PG headgroups in bilayers. Even though the area per lipid in CHARMM36, Slipids, and GROMOS-CKP simulations is in good agreement with experiments (Fig. S6), the experimental increase in POPC headgroup order parameters upon addition of POPG are not fully reproduced (Fig. S3). Therefore we conclude that the counter-ion binding affinity is overestimated in Lipid17 simulations, while the other simulations are more realistic, but slight overbinding cannot be excluded.

Figure S5: Sodium (solid line) and chloride ion density profiles along membrane normal from different simulations with PE lipids.

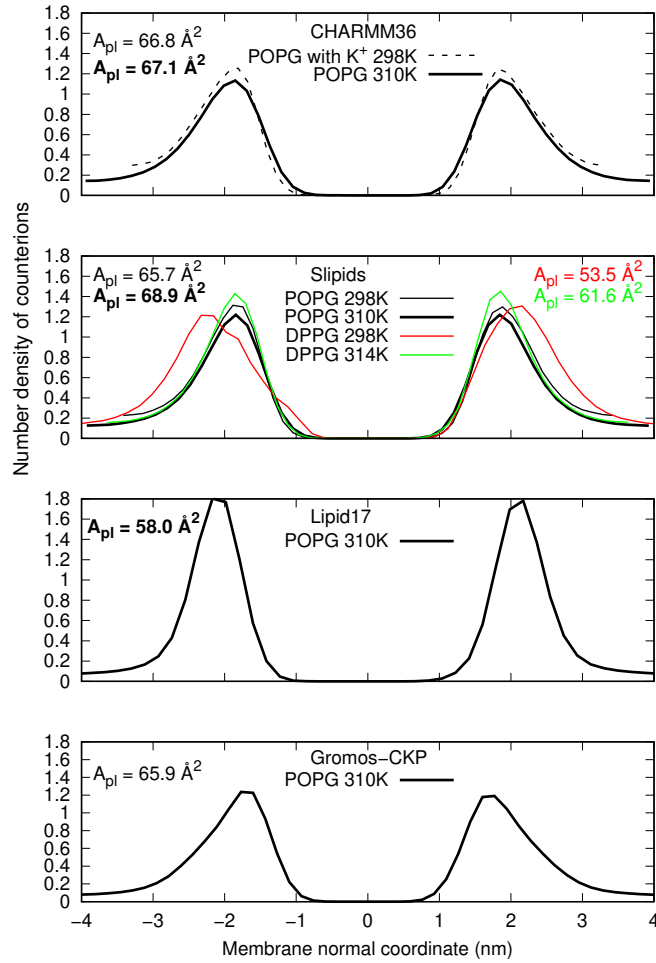

Figure S6: Counterion densities and area per lipids from simulations with PG lipids. Experimental area for POPG at 303 K is 66.1 \AA^2 and 67 \AA^2 for DPPC at 323 K.¹⁵

S2.8 Lipid17

S2.9 ECC-LIPID POPG

In ECC-lipid models, electronic continuum correction (ECC) is applied to implicitly include the missing electronic polarizability into the force field description.^{96,97} In practise, this is implemented by scaling the charges and Lennard-Jones σ s of headgroup, glycerol backbone, and carbonyl regions of Amber Lipid14/17 models are scaled by constant factors. Here, we follow the approach that previously improved ion binding to bilayers containing negatively charged PS lipids:⁹⁷ ECC-POPC parameters (scaling factors $f_q=0.8$ and $f_\sigma=0.89$ applied to Lipid14 POPC parameters)⁹⁶ were used for POPC and scaling factors of $f_q=0.75$ and $f_\sigma=0.89$ were applied to the charges and Lennard-Jones σ s of headgroup, glycerol backbone, and carbonyl regions of Amber Lipid17 POPG parameters. The Lipid17 parameters (described above) and initial configurations were taken from Ref.⁵⁴ with the correct dihedral type, and the resulting parameters are available from Ref. ? . ECC-ion parameters with the scaled charges,⁸⁵⁻⁸⁷ downloaded from bitbucket.org/hseara/ions/src/master/, were used in these simulations.

S3 R-PDLF and SDROSS experiments

Figure S7: (A) Chemical structure of POPE with the labeling of headgroup and glycerol backbone carbons. (B) INEPT spectra from POPE sample with the headgroup and glycerol backbone peaks labeled. (C) 2D R-PDLF spectra (D) Dipolar sliced from the 2D R-PDLF spectra with the resulting order parameters on top of figures. (E) Experimental S-DROSS curves giving signs of the order parameters.

56.A, B etc. labels to be put in the figure.

Figure S8: (A) Chemical structure of POPG with the labeling of headgroup and glycerol backbone carbons. (B) INEPT spectra from POPG sample with the headgroup and glycerol backbone peaks labeled. (C) 2D R-PDLF spectra (D) Dipolar sliced from the 2D R-PDLF spectra with the resulting order parameters on top of figures. (E) Experimental S-DROSS curves giving signs of the order parameters.

Figure S9: Simpson simulation of S-DROSS curve of β -carbon of POPG.

S4 Changes of PG headroup order parameters upon addition of PC

Figure S10: Modulation of PG lipid headgroup order parameters with the increasing amount of PC in lipid bilayer from experiments^{3,6} and simulations with different force fields.

S5 Sodium binding to POPC simulations

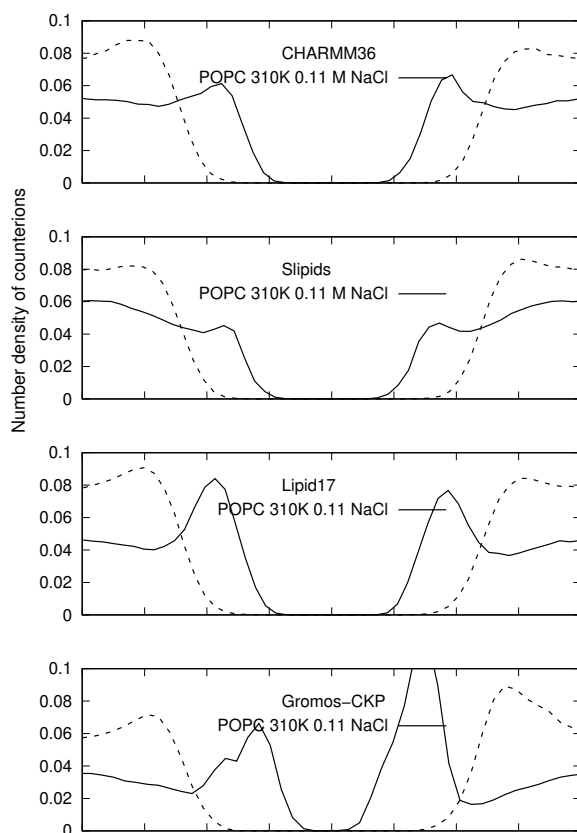

Figure S11: Sodium (solid line) and chloride ion density profiles along membrane normal from different simulations with PC lipids.

57.Discussion about differences to the NMRlipids II to be discussed once we have the details on ions models.

S6 Calcium binding to POPC:POPG (4:1) mixtures

58.Lipid17ecc data to be analyzed and added.

S7 Changes in headgroup conformations upon addition of CaCl_2

Figure S13: Calcium ion density profiles along membrane normal from simulations of POPC:POPG (4:1) mixtures with different force fields.

Figure S14: Changes in POPC Slipids dihedrals with increasing amount of CaCl_2 .

Figure S15: Changes in POPG lipids dihedrals with increasing amount of CaCl_2 .

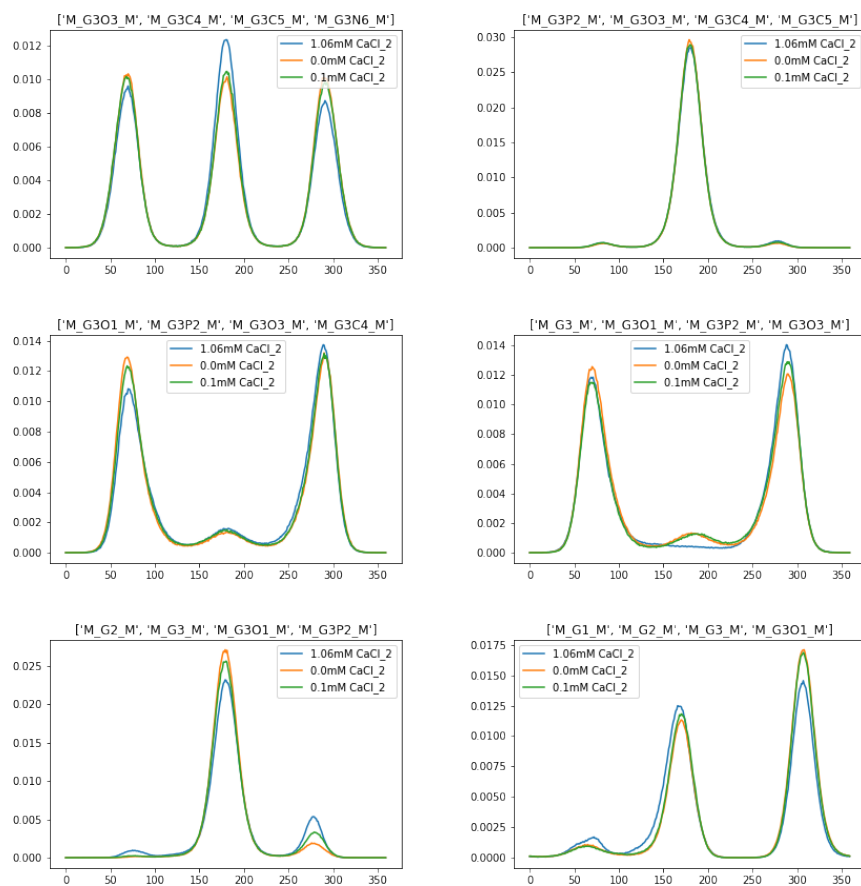

Figure S16: Changes in POPC lipid17 dihedrals with increasing amount of CaCl_2 .

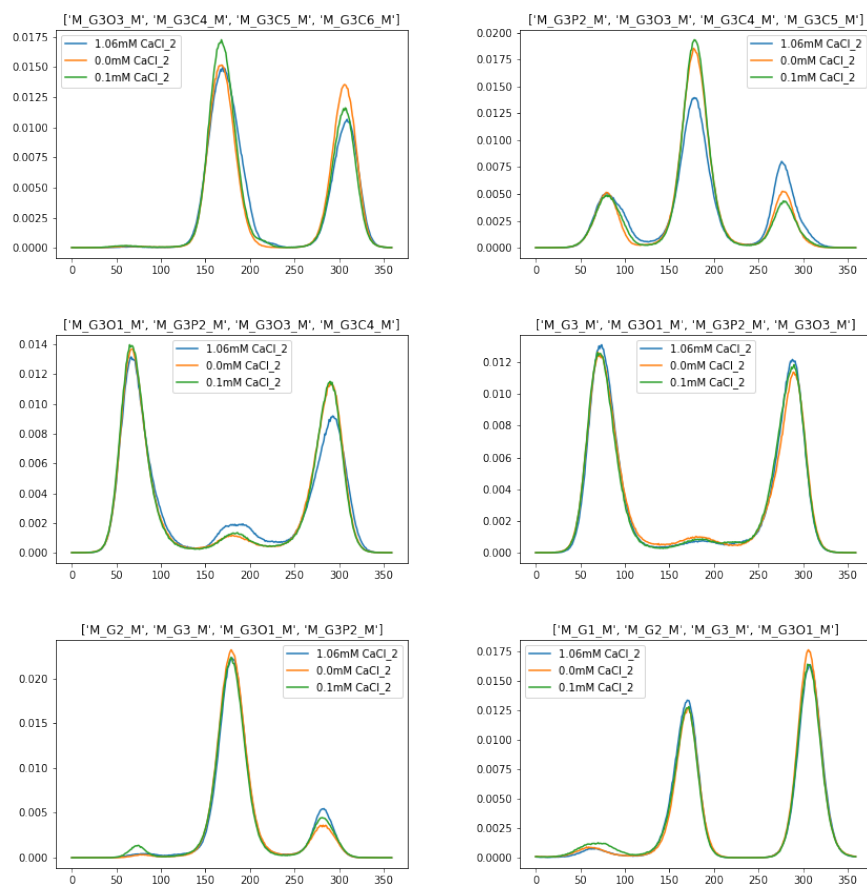

Figure S17: Changes in POPG lipid17 dihedrals with increasing amount of CaCl₂.

Figure S18: Changes in POPC lipid17ecc dihedrals with increasing amount of CaCl_2 .

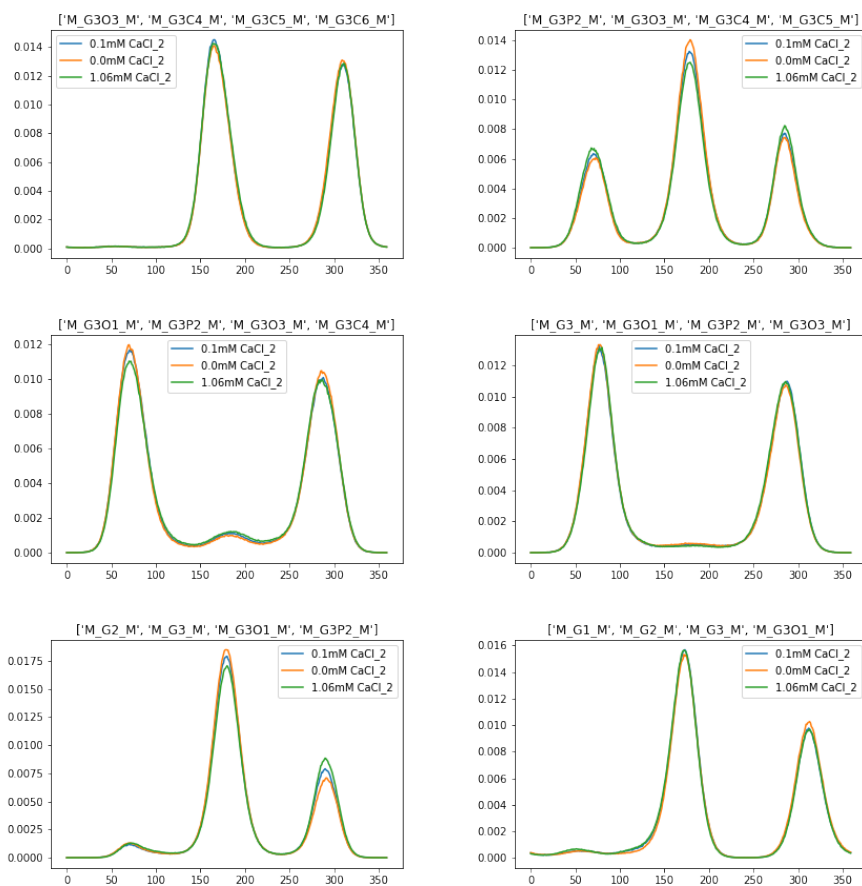

Figure S19: Changes in POPG lipid17ecc dihedrals with increasing amount of CaCl_2 .

Figure S20: Changes in CHARMM36 dihedrals with increasing amount of cationic surfactant.
